# Coulomb phase corrections to the transverse analyzing power $A_{\mathrm{N}}(t)$ in high energy forward proton-proton scattering 

A.A. Poblaguev*<br>Brookhaven National Laboratory, Upton, New York 11973, USA

(Dated: September 30, 2021)

#### Abstract

Study of the polarized proton-proton elastic scattering in the Coulomb Nuclear interference region allows one to measure forward hadronic spin-flip amplitude including the phase. However, in a precision experimental data analysis, a phase shift correction $\delta_{C}$ due to the long distance Coulomb interaction should be taken into account. For the unpolarized scattering, $\delta_{C}$ is commonly considered as well established. Here, we evaluate the Coulomb phase shifts for the spin-flip electromagnetic and hadronic amplitudes. The difference between spin-flip and non-flip Coulomb phase shifts was found to be negligible for current experimental accuracy in the high energy transverse spin elastic $p p$ measurements. However, effective alteration of the hadronic spin-flip amplitude by the long distance electromagnetic corrections can be noticeable.

## I. INTRODUCTION

It is well known that an experimentally determined hadronic scattering amplitude is effectively altered by the accompanying electromagnetic interaction. In the Coulomb-nuclear interference (CNI) region, the protonproton amplitude can be approximated by the following sum of hadronic $\phi(s, t)$ and electromagnetic, $t_{c} / t$, amplitudes [1]

$$
\begin{equation*}
\phi_{p p}^{\mathrm{CNI}}(s, t)=\operatorname{Im} \phi(s, 0)\left[(i+\rho) e^{B t / 2}+\frac{t_{c}}{t} e^{i \delta_{C}+\tilde{B} t / 2}\right] . \tag{1}
\end{equation*}
$$

Here, $\delta_{C}(s, t)$ stands for difference between the electromagnetic and hadronic phases induced by the longdistance Coulomb interaction. Following QED calculations and the optical theorem, $t_{c}=-8 \pi \alpha / \sigma_{\text {tot }}(s)[2]$, where $\alpha$ is the fine structure constant and $\sigma_{\text {tot }}$ is the total $p p$ cross section. Generally, the amplitudes are functions of total energy squared $s$ and momentum transfer squared $t$.

In this paper, numerical estimates will be done for a 100 GeV proton beam (typical for the Relativistic Heavy Ion Collider or the future Electron Ion Collider) scattering on a fixed proton target. Therefore, $\rho=-0.079$ [3], $\sigma_{\text {tot }}=39.2 \mathrm{mb}[3], t_{c}=-1.86 \times 10^{-3} \mathrm{GeV}^{2}$, and $B=$ $11.2 \mathrm{GeV}^{-2}$ [4]. For the sake of simplicity, we do not distinguish between the hadronic $B$ and electromagnetic $\widetilde{B}$ slopes in expressions for the elastic differential cross section

$$
\begin{equation*}
\frac{d \sigma^{e l}}{d t} \propto\left[\left(\frac{t_{c}}{t}\right)^{2}-2\left(\rho+\delta_{C}\right) \frac{t_{c}}{t}+1+\rho^{2}\right] e^{B t} \tag{2}
\end{equation*}
$$

and the analyzing power $A_{\mathrm{N}}(t)$ [Eq. (8)]. We also do not consider small corrections [5] due to Dirac and Pauli form factors and due to the absorption [6].

[^1]For the unpolarized scattering, theoretical understanding of $\delta_{C}(t)$ was developed in many works, in particularly, [7-10].

In Ref. [9], the Coulomb phase was evaluated as

$$
\begin{equation*}
\delta_{C}=-\alpha\left[\ln \frac{-(B+\widetilde{B}) t}{2}+\gamma-\frac{\widetilde{B} t}{2} \ln \frac{-\widetilde{B} t}{2}+\frac{\widetilde{B} t}{4}\right] \tag{3}
\end{equation*}
$$

where $\gamma=0.5772$ is Euler's constant and $\widetilde{B}=8 / \Lambda^{2}=$ $11.2 \mathrm{GeV}^{-2}$ was derived from the ep electromagnetic form factor in dipole form, $\mathcal{F}_{e p}=\left(1-t / \Lambda^{2}\right)^{-2}, \Lambda^{2}=0.71 \mathrm{GeV}^{2}$ [11]. Up to now, this result is commonly used in experimental data analysis.

Neglecting the slopes $B$ and $\widetilde{B}$ dependence on $t$ and omitting the $\mathcal{O}\left(\alpha^{2}\right)$ terms, analytical solution for $\delta_{C}$ was found in Ref. [10]

$$
\begin{align*}
\delta_{C}=\alpha \times\{ & \ln \frac{\widetilde{B}^{2}}{B^{2}}+E i\left(\frac{2 B^{2} / \widetilde{B}}{B+\widetilde{B}} w\right)-E i(w) \\
& \left.+e^{2 w}\left[2 E_{1}(2 w)-E_{1}(w)\right]\right\} \tag{4}
\end{align*}
$$

where $w=|\widetilde{B} t| / 4$ and

$$
\begin{equation*}
\widetilde{B}=\frac{2}{3} r_{E}^{2}=12.1 \mathrm{GeV}^{-2} \tag{5}
\end{equation*}
$$

was expressed via rms charge radius of a proton, $r_{E}=$ $0.841 \mathrm{fm}[12]$. In terms of $B$ and $\widetilde{B}$, Eqs. (3) and (4) are in agreement for low $t$.

It was shown in Ref. [13] that Coulomb phase should be independent of the helicity structure of the scattering amplitudes. However, the conclusion made was actually relevant only for the leading term $\sim \ln |t|$ in $\delta_{C}(t)$.

In this paper we adapt formulas derived in Ref. [10] to evaluate Coulomb phases in the spin-flip scattering. Consequent alteration of the expression [14] for forward elastic $p p$ analyzing power $A_{\mathrm{N}}(t)$ will be discussed.

FIG. 1. Three types of the elastic $p p$ scattering: (C) electromagnetic including multiple photon exchange, (N) bare hadronic, and (NC) combined hadronic and electromagnetic.

## II. HIGH ENERGY FORWARD ELASTIC $p p$ ANALYZING POWER

For a CNI elastic scattering of a vertically polarized proton beam $p^{\uparrow} p$, the analyzing power $A_{N}$ is caused by interference of the non-flip ( $n f$ ) and spin-flip ( $s f$ ) amplitudes [2, 13, 14]

$$
\begin{equation*}
A_{N}=\frac{2 \operatorname{Im}\left[\widetilde{\phi}_{s f} \phi_{n f}^{*}+\phi_{s f} \widetilde{\phi}_{n f}^{*}+\phi_{s f} \phi_{n f}^{*}\right]}{\left|\phi_{n f}+\widetilde{\phi}_{n f}\right|^{2}} \tag{6}
\end{equation*}
$$

Here, hadronic $\phi$ and electromagnetic $\widetilde{\phi}$ parts of an amplitude are discriminated by tilde symbol.

The $s f$ amplitudes can be simply related to the $n f$ ones:

$$
\begin{equation*}
\widetilde{\phi}_{s f} / \widetilde{\phi}_{n f}=\frac{\kappa_{p}}{2} \sqrt{-t} / m_{p}, \quad \phi_{s f} / \phi_{n f}=\frac{r_{5}}{i+\rho} \sqrt{-t} / m_{p} \tag{7}
\end{equation*}
$$

where $\kappa_{p}=\mu_{p}-1=1.973$ is anomalous magnetic moment of a proton, $\left|r_{5}\right|=\left|R_{5}+i I_{5}\right| \sim 0.02$ [15] is hadronic spin-flip parameter [14], and $m_{p}$ is a proton mass. Consequently,

$$
\begin{align*}
A_{\mathrm{N}}(t) & =\frac{\sqrt{-t}}{m_{p}} \times \\
& \frac{\left[\kappa_{p}\left(1-\delta_{C}^{e m} \rho\right)-2\left(I_{5}-\delta_{C}^{h} R_{5}\right)\right] \frac{t_{c}}{t}-2\left(R_{5}+\rho I_{5}\right)}{\left(\frac{t_{c}}{t}\right)^{2}-2\left(\rho+\delta_{C}\right) \frac{t_{c}}{t}+1+\rho^{2}} \tag{8}
\end{align*}
$$

where non-flip phase $\delta_{C}$ is given in Eq. (4) while $\delta_{C}^{e m}$ and $\delta_{C}^{h}$ are spin-flip phase shifts in $\widetilde{\phi}_{s f} \phi_{n f}^{*}$ and $\phi_{s f} \widetilde{\phi}_{n f}^{*}$ interference terms, respectively.

All recent experimental studies $[15,16]$ of the forward elastic proton-proton $A_{\mathrm{N}}(t)$ were based on Eq. (8) with $\delta_{C}^{e m}=\delta_{C}^{h}=\delta_{C}$.

## III. SPIN-FLIP COULOMB PHASES IN ELASTIC $\boldsymbol{p}^{\uparrow} \boldsymbol{p}$ ANALYZING POWER

To evaluate spin-flip $\delta_{C}^{e m}$ and $\delta_{C}^{h}$, we adapt the expressions which were derived in Ref. [10] to calculate $\delta_{C}$.

## A. The theoretical approach [10] used to calculate Coulomb corrections to the non-flip amplitudes

Considering multiple photon exchange in the elastic $p p$ scattering and neglecting the higher order corrections
$\mathcal{O}\left(\alpha^{3}\right)$, the net long range Coulomb (C) amplitude (see Fig.1) can be presented as [10]

$$
\begin{align*}
f_{C}\left(q_{T}\right) & =\frac{i}{2 \pi} \int d^{2} b e^{i \vec{q}_{T} \vec{b}}\left[1-e^{i \chi_{C}^{n f}(b)}\right]  \tag{9}\\
& =\hat{f}_{C}\left(q_{T}\right)+\frac{i}{2 \pi} \int d^{2} b e^{i \vec{q}_{T} \vec{b}}\left[\chi_{C}(b)\right]^{2} / 2 \tag{10}
\end{align*}
$$

where $q_{T} \approx \sqrt{-t}$ is transverse momentum and the eikonal phase

$$
\begin{equation*}
\chi_{C}^{n f}(b)=\frac{1}{2 \pi} \int d^{2} q_{T} \hat{f}_{C}\left(q_{T}\right) e^{-i \vec{q}_{T} \vec{b}} \tag{11}
\end{equation*}
$$

is a Fourier transform of the Coulomb part of the amplitude calculated in Born approximation [10]

$$
\begin{equation*}
\hat{f}_{C}\left(q_{T}\right)=\frac{-2 \alpha}{q_{T}^{2}+\lambda^{2}} e^{-\widetilde{B} q_{T}^{2} / 2} \tag{12}
\end{equation*}
$$

Here, the amplitude is defined as sum of two non-flip helicity amplitudes $\langle++\mid++\rangle$ and $\langle+-\mid+-\rangle[14]$. A small photon mass $\lambda$ was included to Eq. (12) to keep the integrals finite.

The multi-photon exchange results in an acquired Coulomb phase $\Phi_{C}\left(q_{T}\right)$

$$
\begin{equation*}
f_{C}\left(q_{T}\right)=\hat{f}_{C}\left(q_{T}\right) e^{i \Phi_{C}\left(q_{T}\right)} \tag{13}
\end{equation*}
$$

Assuming $\Phi_{C}\left(q_{T}\right) \ll 1$, one finds

$$
\begin{align*}
\Phi_{C}\left(q_{T}\right) & =-i\left[f_{C}\left(q_{T}\right) / \hat{f}_{C}\left(q_{T}\right)-1\right]  \tag{14}\\
& =\frac{1}{4 \pi} \int d^{2} q_{1} d^{2} q_{2} \delta\left(\vec{q}_{T}-\vec{q}_{1}-\vec{q}_{2}\right) \frac{\hat{f}_{C}\left(q_{1}\right) \hat{f}_{C}\left(q_{2}\right)}{\hat{f}_{C}\left(q_{T}\right)} \tag{15}
\end{align*}
$$

Similarly, to calculate the Coulomb corrections to the hadronic amplitude

$$
\begin{equation*}
\hat{f}_{N}\left(q_{T}\right)=\frac{(i+\rho) \sigma_{\mathrm{tot}}}{4 \pi} e^{-B q_{T}^{2} / 2} \tag{16}
\end{equation*}
$$

one can use the following relations:

$$
\begin{align*}
f_{\mathrm{NC}}\left(q_{T}\right) & =\frac{i}{2 \pi} \int d^{2} b e^{i \vec{q}_{T} \vec{b}} \gamma_{N}^{n f}(b) e^{i \chi_{C}^{n f}(b)}  \tag{17}\\
& =\hat{f}_{N}\left(q_{T}\right)+\frac{i}{2 \pi} \int d^{2} b e^{i \vec{q}_{T} \vec{b}} \gamma_{N}^{n f} \chi_{C}^{n f}  \tag{18}\\
\gamma_{N}^{n f}(b) & =\frac{-i}{2 \pi} \int d^{2} q_{T} e^{-i \vec{q}_{T} \vec{b}} \hat{f}_{N}\left(q_{T}\right)  \tag{19}\\
\Phi_{\mathrm{NC}}\left(q_{T}\right) & =-\frac{\alpha}{\pi} \int \frac{d^{2} q_{1}}{q_{1}^{2}+\lambda^{2}} \\
& \times \exp \left[-(B+\widetilde{B}) q_{1}^{2} / 2+B \vec{q}_{1} \overrightarrow{q_{T}} \cdot\right] \tag{20}
\end{align*}
$$

Eqs. (15) and (20) were analytically integrated in Ref. [10]. Both, $\Phi_{C}\left(q_{T}\right)$ and $\Phi_{\mathrm{NC}}\left(q_{T}\right)$, contains the divergent term $\ln q^{2} / \lambda^{2}$ which, however, is canceled in the final expression for the Coulomb phase difference

$$
\begin{equation*}
\delta_{C}(t)=\Phi_{C}(t)-\Phi_{\mathrm{NC}}(t) \tag{21}
\end{equation*}
$$

displayed in Eq. (4).

## B. Coulomb corrections to the spin-flip amplitudes

To find the Coulomb corrected spin-flip amplitudes $f_{C}^{s f}\left(q_{T}\right)$ and $f_{\mathrm{NC}}^{s f}\left(q_{T}\right)$, one can use the following eikonal phases [17]

$$
\begin{equation*}
\chi_{C}^{s f}(b)=\frac{1}{2 \pi} \int d^{2} q e^{-i \vec{q} \vec{b}} \times \frac{\kappa_{p}}{2 m_{p}}(\vec{n} \vec{q}) \hat{f}_{C}(q) / 2 \tag{22}
\end{equation*}
$$

and

$$
\begin{equation*}
\gamma_{N}^{s f}(b)=\frac{-i}{2 \pi} \int d^{2} q e^{-i \vec{q} \vec{b}} \times \frac{r_{5}}{(i+\rho) m_{p}}(\vec{n} \vec{q}) \hat{f}_{N}(q) / 2 \tag{23}
\end{equation*}
$$

respectively. Here, $\vec{n} \propto \vec{p}_{\text {beam }} \times \vec{s}$ is a unit vector orthogonal to the beam momentum $\vec{p}_{\text {beam }}$ and the proton spin $\vec{s}$.

Considering the spin flip amplitudes for $\vec{q}_{T}=\vec{n} q_{T}$, one can readily determine the spin-flip phase $\Phi_{C}^{s f}\left(q_{T}\right)$ by adding factor $2\left(\vec{q}_{T} \vec{q}_{1}\right) / q_{T}^{2}$ or $2\left(\vec{q}_{T} \vec{q}_{2}\right) / q_{T}^{2}$ to integral (15). Since $\vec{q}_{1} \vec{q}_{T}+\vec{q}_{2} \vec{q}_{T}=q_{T}^{2}$, we immediately find

$$
\begin{equation*}
\Phi_{C}^{s f}\left(q_{T}\right)=\Phi_{C}\left(q_{T}\right) \tag{24}
\end{equation*}
$$

which leads to

$$
\begin{equation*}
\delta_{C}^{e m}(t)=\delta_{C}(t) \tag{25}
\end{equation*}
$$

To calculate $\Phi_{\mathrm{NC}}^{s f}$, factor $\left(\vec{q}_{2} \vec{q}_{T}\right) / q_{T}^{2}=1-\left(\vec{q}_{1} \vec{q}_{T}\right) / q_{T}^{2}$ should be added to Eq. (20), which gives

$$
\begin{align*}
\Phi_{\mathrm{NC}}^{s f}\left(q_{T}\right) & =\Phi_{\mathrm{NC}}\left(q_{T}\right)-\frac{\alpha B}{B+\widetilde{B}} \times \Delta_{\mathrm{NC}}^{s f}(\eta)  \tag{26}\\
\Delta_{\mathrm{NC}}^{s f}(\eta) & =\int_{0}^{\infty} \frac{d u}{\eta} e^{-u^{2} / 4 \eta} \int_{-\pi}^{\pi} \frac{d \varphi}{2 \pi} \cos \varphi e^{u \cos \varphi}  \tag{27}\\
\eta & =\frac{B}{B+\widetilde{B}} \times \frac{B q_{T}^{2}}{2} \approx B q_{T}^{2} / 4 \tag{28}
\end{align*}
$$

Expanding

$$
\begin{equation*}
e^{u \cos \varphi} \cos \varphi \rightarrow \sum_{k=0}^{\infty} \frac{u^{k}}{k!} \cos ^{k+1} \varphi \tag{29}
\end{equation*}
$$

and using the following integrals [18]

$$
\begin{align*}
\int_{-\pi}^{\pi} \cos ^{2 n+1} x d x & =0  \tag{30}\\
\int_{-\pi}^{\pi} \cos ^{2 n} x d x & =\frac{\pi}{2^{n-2}} \frac{(2 n-1)!}{(n-1)!n!}  \tag{31}\\
\int_{0}^{\infty} x^{2 n+1} e^{-p x^{2}} d x & =\frac{n!}{2 p^{n+1}} \tag{32}
\end{align*}
$$

one arrives to

$$
\begin{equation*}
\Delta_{\mathrm{NC}}^{s f}(\eta)=\sum_{k=0}^{\infty} \frac{\eta^{k}}{(k+1)!}=\frac{e^{\eta}-1}{\eta} \tag{33}
\end{equation*}
$$

Thus,

$$
\begin{equation*}
\delta_{C}^{h}(t)=\delta_{C}(t)-\frac{\alpha B}{B+\widetilde{B}} \frac{e^{\eta}-1}{\eta} \tag{34}
\end{equation*}
$$

In Ref. [6], it was pointed out that hadronic spin-flip amplitude should also include the spin-flip photon exchange, i.e. one should replace

$$
\begin{equation*}
\gamma_{N}^{s f}(b) \rightarrow \gamma_{N}^{s f}(b)+i \chi_{C}^{s f}(b) \gamma_{N}^{n f}(b) \tag{35}
\end{equation*}
$$

in Eq. (19). Using Eq. (26), one readily finds

$$
\begin{align*}
& \frac{i}{2 \pi} \int d^{2} b e^{i \vec{q}_{T} \vec{b}} \chi_{C}^{s f}(b) \gamma_{N}^{n f}(b) \\
& \quad=\frac{\kappa_{p}\left[\Phi_{N}\left(q_{T}\right)-\Phi_{N}^{s f}\left(q_{T}\right)\right]}{2 m_{p}}\left(\vec{n} \vec{q}_{T}\right) \hat{f}_{N}\left(q_{T}\right) \tag{36}
\end{align*}
$$

Thus, replacement (35) can be interpreted as an effective alteration of the hadronic spin-flip parameter

$$
\begin{gather*}
r_{5} \rightarrow r_{5}+i(i+\rho) \Delta_{\gamma} \approx r_{5}-\Delta_{\gamma}  \tag{37}\\
\Delta_{\gamma}=\frac{\alpha \kappa_{p} B}{2(B+\widetilde{B})} \approx 0.003 \tag{38}
\end{gather*}
$$

For the corrected $r_{5}$, Coulomb phase $\Phi_{\mathrm{NC}}^{s f}(t)$ is the same as in Eq. (26).

## IV. SUMMARY

Adapting the technique developed in Ref. [10], the Coulomb phase shifts in the elastic $p p$ spin-flip amplitude interferences $\widetilde{\phi}_{s f} \phi_{n f}^{*}(25)$ and $\phi_{s f} \widetilde{\phi}_{n f}^{*}(34)$ were calculated.

Small difference, $\delta_{C}^{h}-\delta_{C} \sim-\alpha / 2$, was found for the CNI scattering $|t| \lesssim 0.1 \mathrm{GeV}^{2}(\eta<0.3)$. Since $\left|R_{5}\right| \lesssim$ 0.02 , such a discrepansy can be neglected in expression (8) for $A_{\mathrm{N}}(t)$.

Thus, we can agree with the Coulomb phases approximation

$$
\begin{equation*}
\delta_{C}^{e m}=\delta_{C}^{h}=\delta_{C}=-\alpha \times\left[\ln \frac{(B+\widetilde{B})|t|}{2}+\gamma\right] \tag{39}
\end{equation*}
$$

suggested in Ref. [14].
Evaluating $\delta_{C}^{e m}$ and $\delta_{C}^{h}$, we did not distinguish between non-flip $B$ and spin-flip $B_{s f}$ slopes as well as between $\widetilde{B}_{s f}$ and

$$
\begin{equation*}
\widetilde{B}_{s f}=\left(r_{E}^{2}+r_{M}^{2}\right) / 3 \tag{40}
\end{equation*}
$$

where $r_{M}=0.851 \pm 0.026 \mathrm{fm}$ [19] is magnetic radius of a proton.

Using explicit expressions for $\Phi_{C}(t)$ and $\Phi_{N}(t)$ [10] one can derive

$$
\begin{align*}
\delta_{C}^{e m}\left(t, \widetilde{B}_{s f}, B\right)= & \delta_{C}(t, \widetilde{B}, B)+\mathcal{O}\left(\left|\widetilde{B}_{s f}-\widetilde{B}\right| t\right)  \tag{41}\\
\delta_{C}^{h}\left(t, \widetilde{B}, B_{s f}\right)= & \delta_{C}(t, \widetilde{B}, B)-\frac{\alpha B_{s f}}{B_{s f}+\widetilde{B}} \\
& +\alpha \ln \frac{B+\widetilde{B}}{B_{s f}+\widetilde{B}}+\mathcal{O}\left(\left|B_{s f}-B\right| t\right) \tag{42}
\end{align*}
$$

For a reasonable ratio $B_{s f} / B$ between the spin-flip and non-flip slopes [20], the related corrections to $\delta_{C}^{e m}$ and $\delta_{C}^{h}$ can be neglected in the experimental data analysis.

Spin-flip photon exchange (35) results in the correction

$$
\begin{equation*}
\Delta \operatorname{Re} r_{5}=-\Delta_{\gamma} \approx-0.003 \tag{43}
\end{equation*}
$$

to the value of the hadronic spin-flip parameter $r_{5}$. The correction found is about triple of the experimental accuracy for $R_{5}$ in the HJET measurements [15]. Thus, the
published values of $R_{5}$ [15] should be corrected,

$$
\begin{equation*}
\operatorname{Re} r_{5}=\operatorname{Re} r_{5}^{\text {meas }}+\Delta_{\gamma} \tag{44}
\end{equation*}
$$

This is especially important for the Regge fit of the hadronic spin-flip amplitudes.

It is interesting to note that an absorptive correction,

$$
\begin{equation*}
a_{s f}=\alpha B /\left(B+\widetilde{B}_{s f}\right), \tag{45}
\end{equation*}
$$

to the electromagnetic spin-flip form factor, $\mathcal{F}_{p p}^{s f}(t) \rightarrow$ $\mathcal{F}_{p p}^{s f}(t) \times\left(1+a_{s f} t / t_{c}\right)$, results [5] in the same effective alteration of $r_{5}$ as shown in Eq. (43).
