# Analytical Field Calculation of the Direct Wind Helical Dipole

T. Tominaka (RIKEN, Japan)

## 1. Introduction

The magnetic field of a prototype of the direct wind helical dipole fabricated at AML, Inc. under contract with BNL, is calculated analytically and numerically in this paper. The analytical calculation is compared with the numerical calculation by the Biot and Savart's Law in the case without iron yoke. The purpose of this paper is to obtain the contents of multipoles expected for the direct wind helical dipole.

## 2. Shape of a Direct Wind Helical Dipole Magnet

A schematic views of some portions of this superconducting helical dipole are shown in Fig.1. The cross sections at  $z=0$  and  $z=0.4$  m of this superconducting helical dipole are shown in Figs.2 and 3, respectively. All 1866 black dots shown in Figs.2 and 3 correspond to superconducting strands used as conductors. These figures are derived from the data of 202524 points about the helical dipole coil with 11 layers. Then, the central or average angle of both coil blocks can be obtained as the average of every conductor's angle in each block. In addition, the  $z$  dependence of the central angle of both coil blocks is obtained, as shown in Figs.4 and 5. By fitting, the  $z$  [m] dependence of the central angle,  $\theta_r(z)$ ,  $\theta_l(z)$  [rad] of the right and left coil block at  $z=0$  are as follows,

$$\begin{cases} \theta_r(z) = 0.00376105 + 2.51957 z + 8.03707 \cdot 10^{-6} z^2 - 0.0000319832 z^3 \\ \theta_l(z) = 3.13783 + 2.51957 z - 8.03707 \cdot 10^{-6} z^2 - 0.0000319832 z^3 \end{cases} \quad (1)$$

From this equation, it results that  $k=2\pi/L=2.52$  rad/m, and  $\theta_r(z=0) > 0$  and  $\theta_l(z=0) < \pi$ , where  $L$  is the pitch length. Then, it is realized that both coil blocks are wholly little bit closer to the upper pole than the lower pole at  $z=0$ . As a result, it is expected that this prototype of the direct wind helical dipole has the skew multipoles.

## 3. Magnetic Field of a Direct Wind Helical Dipole Magnet

For the case of current,  $I = 420$  A, without iron yoke, the magnetic field of this prototype of the direct wind helical dipole magnet is calculated numerically with the Biot and Savart's Law from the data of 202524 points, as shown in Figs.6 and 7. The conventional normal multipole coefficients can also be derived by fitting from the  $y$  component of magnetic field,  $B_y$ , on the  $x$ -axis as shown in Fig.6. The resultant expression is as follows,

$$B_y(r=x, \theta=0, z=0) = 2.366 \left\{ 1 - 0.0121 \left(\frac{x}{r_0}\right)^2 - 0.0117 \left(\frac{x}{r_0}\right)^4 + 0.00356 \left(\frac{x}{r_0}\right)^6 - 7.9 \cdot 10^{-4} \left(\frac{x}{r_0}\right)^8 + 4.3 \cdot 10^{-4} \left(\frac{x}{r_0}\right)^{10} \right\} \quad (2)$$

In addition, the conventional normal and skew multipole coefficients for the reference radius  $r_0 = 30$  mm, from the  $y$ -directional magnetic field  $B_y$  on the circle of radius  $r = 30$  mm can be derived with the Fourier analysis, as shown Table 1. For example, the conventional sextupole coefficients  $b_3 = -0.0121$  derived from the field distribution of  $B_y$  on  $x$ -axis is different from  $b_3 = -0.0136$  derived from the field distribution on the circle due to the helical structure.

The normal and skew contents of helical multipole with the reference radius  $r_0 = 30$  mm, can be analytically calculated from the distribution of the radial magnetic field  $B_r$ , the azimuthal magnetic field  $B_\theta$ , and the  $z$ -directional magnetic field  $B_z$  on the circle of radius  $r = 30$  mm calculated numerically with the Biot and Savart's Law, as shown in Table 2.

Furthermore, in the case without iron yoke, the magnetic field of a direct wind helical dipole magnet can be calculated analytically with the assumption of the infinite length with the coil twist of  $k=2.52$  rad/m. For the comparison, the analytically calculated contents of helical multipole expected for this helical dipole together with the 2-dimensional multipole coefficients of the 2-dimensional structure for the reference radius  $r_0 = 30$  mm, are shown in

Tables 3 and 4, respectively. From comparison between Tables 2 and Table 3, it is realized that the analytical results are almost consistent with those obtained numerically with the Biot and Savart's Law for this prototype of the direct wind helical dipole. The twist (or  $k$ ) dependence of the reference field  $B_{ref}(k)$ , the helical skew quadrupole coefficient,  $a_2(k)$ , and the helical normal sextupole coefficient,  $b_3(k)$ , are shown in Figs.8, 9 and 10, respectively.

In the case with iron yoke of the inner diameter of 127.6 mm, similarly, the analytically calculated contents of helical multipole expected for this helical dipole together with the 2-dimensional multipole coefficients of the 2-dimensional structure for the reference radius  $r_0 = 30$  mm, are shown in Tables 5 and 6, respectively. The twist (or  $k$ ) dependence of the reference field  $B_{ref}(k)$ , the helical skew quadrupole coefficient,  $a_2(k)$ , and the helical normal sextupole coefficient,  $b_3(k)$ , are also shown in Figs.11, 12 and 13, respectively.

#### 4. Conclusion

The contents of multipole expected for a prototype of the direct wind helical dipole are obtained analytically, with the comparison between helical multipoles and 2-dimensional multipoles. The analytical results are almost consistent with those obtained with the Biot and Savart's Law. It seems that the contents of multipole expected for this prototype of the direct wind helical dipole are much larger than those of the slotted helical dipole. This should be investigated experimentally with the field measurement.

#### 5. Acknowledgments

Special thanks go to AML, Inc. and BNL for providing us with a wealth of information on the RHIC helical dipole magnets. The author is also indebted for helpful discussions and comments to Prof. T. Katayama of Institute of Nuclear Physics, University of Tokyo and RIKEN and Dr. M. Okamura of BNL/RIKEN.
