## A METHOD FOR PREPARING INPUT FILES FOR THE POISSON CODES

A. Kponou

August 22, 1990
Corrigendum, November 19, 1991

#### Abstract

A method is suggested for preparing input files for AUTOMESH, the first of the POISSON programs. Boundary points used to define the regions in a problem are given labels which are associated with the coordinates of the points. The '\$PO' lines are then written with the labels instead of the coordinates. A suitable program then reads the file, replaces the labels with the coordinates, and prepares an output file in the standard format.

## INTRODUCTION

At present, preparing an input file for AUTOMESH, the first of the POISSON program, requires that the coordinates of boundary points of the different regions of the problem be entered as often as these points occur. Moreover, if one or more boundary points are changed--changing the shape of the regions--the coordinates must be changed wherever these points occur.

In the approach suggested here, a unique label is associated with each boundary point, and the coordinates of the points are given at the same time. A computer program then reads the file and substitutes the coordinates of a point wherever the label of that point is encountered--in the lines beginning with '\$PO'. An output file, without the label definitions, is saved for use as the input to AUTOMESH.

The advantages of this approach are:
i. The coordinates of a point are entered only once.
ii. Any change in the coordinates of a point is made at only one location--the label definition for that point.

An input file can therefore be prepared and modified much faster, and the chances for typographical errors are significantly reduced.

## IMPLEMENTATION

## REXX (IBM 3090 and PC)

The scheme was first tried out with the REXX language on the IBM 3090. A program was written by H. Berry of the Brookhaven Computing \& Communications Division (CCD) to do the conversion. It was later modified to run on a PC using Personal REXX, 1 the PC implementation of the language. Listings of both versions of the program are given in Appendices A and B. An example of an input file is given in Figure 1.

The labels have the root, "POINT", and a number which REXX uses as an array index. Lines beginning with "\$PO" are searched for a label, which is then replaced with its associated coordinates. Lines not starting with "POINT" or "\$PO", except for the delimiter $\$ \$$, are copied to the output file, which is also reproduced in Figure 1.

The output file was successfully processed by AUTOMESH on the VAX Cluster at CCD.

DCL (VAX/VMS)
DCL on the VAX also has similar string manipulation capabilities. A program in this language was written by J. Bennett of CCD. It is listed in Appendix C.

## DISCUSSION

The scheme proposed for simplifying preparation of the input file for AUTOMESH has been successfully implemented on three classes of widely used computers, without modifying AUTOMESH in any way. A FORTRAN program to do the same thing appeared to be very complicated to write; manipulating character strings is not one of FORTRAN's strengths.

EXEC (IBM 3090), COM (VAX), and BATCH (PC) files can be written for "single pass" operation, where AUTOMESH is executed immediately after the file has been converted to standard format. Passing the input and output file names as parameters in the program execution command gives complete flexibility in naming them.

Readers familiar with the code MAD ${ }^{2}$ will recognize a similarity between the work described here and the way a beam line is set up there. The idea for this work came to me after I started using MAD.

## ACKNOWLEDGMENTS

At the outset, I considered using FORTRAN, then EDT Macros on the VAX, but felt there had to be a "neater" way. H. Berry demonstrated a REXX solution in under an hour. Later, J. Bennett did the same with DCL. F. DeVito and C. Rohrig (a summer student) of CCD also graciously helped.

```

The VAX program given in Appendix $C$ has a bug. It incorrectly substitutes for labels with indices of 10 or higher. For example, when cnt=1, the lexical f\$locate correctly locates the string POINT1 in the label POINT10, and the coordinates for POINT1 - in the string point1 - are substituted for POINT10 in the \$PO line. The following program solves the problem. Use of the f\$element lexical function has also simplified and shortened the program. All data must start in column two or higher, and for the \$PO cards, there should be at least one blank space on either side of the label string.

```
$ set noverify
$ set noon
