CALCULATED FORMULAS FOR CONTROLLING THE AGS TUNE

AGS Accelerator Division Technical Note 455 documented the field measurements for a typical AGS high field tune quadrupole. This note documents calculations of the formulas to be used with these magnets. Figures 1 thru 6 show plots of the MAD calculated tunes versus the quadrupole currents at injection, transition, and extraction. To the accuracy used in the AGS these lines are all straight. The momentum dependence of the measured slopes is very linear. The results can be summarized in the equations:

$$\begin{aligned}P * \Delta Q_x &= m_{11} * I_h + m_{12} * I_v \\P * \Delta Q_y &= m_{21} * I_h + m_{22} * I_v\end{aligned}$$

where:

P = the momentum in GeV/c
 ΔQ_x = the change in the horizontal tune
 ΔQ_y = the change in the vertical tune
 I_h = the current in the horizontal quadrupoles in Amperes
 I_v = the current in the vertical quadrupoles in Amperes

The table gives the results:

	VALUE	STD
m_{11}	.01071	$3.81 * 10^{-5}$
m_{12}	-.00521	$2.84 * 10^{-5}$
m_{21}	-.00517	$3.1 * 10^{-5}$
m_{22}	.01072	$2.46 * 10^{-5}$

These results are in good agreement with the empirical numbers used in the AGS tune control program.

It is convenient to record the inverse of these equations:

$$\begin{aligned}I_h &= 121.9908 * P * \Delta Q_x + 58.83324 * P * \Delta Q_y \\I_v &= 59.28843 * P * \Delta Q_x + 121.877 * P * \Delta Q_y\end{aligned}$$

Q vs. Iv
