Coarse Aperture Study for the Window Frame Dipoles in RHIC+

Armando Antillon

June 22, 1984

Abstract.

We use PATRICIA to study the quality of the multipolar contribution sin the Window Frame Dipoles (WFD). In order to avoid possible noise with insetions, we only use 81 characteristic RHIC cell. As we want to make a comparison with available information on the Dedicated RHIC dipoles (DRD), we only determine the apperture of WFD for some values of $\Delta P/\rho_{\rm m}$.

This exercise is made in order to provide information, from the dynamical point of view, of possible magnets to be used in RHIC. This study has already been made for the dedicated RHIC dipoles 1, and we will take it as reference to compare the WFD results. The structure of the cells are of the FODO type with a dipole (10.7m) in between. Two families of sextupoles (with zero lenght) have been used to correct the natural cromaticity to a zero value. One family is in the center of the focusing quadrupole and the other in the center of the defocusing quadrupole. The multipolar contribution to ideal dipoles is simulated with zero lenght multipoles in the edges of dipoles. This is a rough approach, and work to take a better integration along dipoles is under progress.

Usually people in magnet design use coefficients (b) that give directly the deviation of the field, respect B, in a certain reference point, i.e.

$$\frac{B}{B_o} = \sum_{n} b_n \left(\frac{x}{x_o}\right)^n$$
, where x_o is the reference point,

while Patricia use as input coefficients by given by

$$\frac{B}{B_o} = \sum_{n} b_n x^n$$

The obvious relation between them is

$$b_n = \frac{b_n}{x_n}$$

The coefficients on have been provided by J.Jackson, and for low field dopoles

(1.9T) they are as follows (others with are not shown are zero for n € 22)

n	bn x 10 ⁴ (at 2.54 cm)	ejî .bh silyase
4	08	-19.2201
6.33	o .08 <i>€</i> o.	2.9791x10 ⁴
8	dp# 55 - 02. ; √ - 1	1.15441x10 ⁷
18 ,	.01 .	5.16408x10 ²²
20:	01	-8.00434×10^{25}

The quality of the dipole field is measured making a comparision between maximum beam size for ideal magnets (no multipoles) and maximum beam size when multipoles are included. The beam size in one direction is determined with the emittance and the β function as $\mathcal{U}(s) = \sqrt{\frac{\epsilon u \beta u(s)}{\pi}}$

For a given aperture of the elements in the ring, we count the number of turns that a particle can give in the ring without exceed in amplitude the aperture important and the ring without exceeds in amplitude the aperture important and the ring without exceeds in amplitude the aperture important and the ring without exceeds in amplitude the aperture important and the ring without exceeds in amplitude the aperture important and the ring without exceeds in amplitude the aperture important and the ring without exceeds in amplitude the aperture important and the ring without exceeds in amplitude the aperture important and the ring without exceeds in amplitude the aperture important and the ring without exceeds in amplitude the aperture important and the ring without exceeds in amplitude the aperture important and the ring without exceeds in amplitude the aperture important and the ring without exceeds in amplitude and the ring without exceeds and t

this physical barrier is made too large (1000 mm), we will have information about the dynamical stability of the beam, i.e. the dynamical aperture.

We chose in PATRICIA a reference emittance of $\epsilon_0 = 0.5 \, \text{TeV} \, 10^5 \, \text{We-rad}$ in terms of its units, emittance is controlled by a parameter A in the way $= \left(\frac{A}{10}\right)^{2} \in S.$

$$\epsilon = \left(\frac{A}{10}\right)^2 \epsilon_0$$

Changing A we can see the number of turns a particle can give in the ring.

Dynamical Aperture of Dipoles.

We will present results in the same way as in 1).

- A has the same meaning as before.
- B is the number of turns the particle will give if its amplitude does not exceed the aperture given.
- Colis the number of turns the particle gives in the ring. D=beam size= $(x^2+y^2)^{\frac{1}{2}}$. With $E = E_X = E_Y$, $D = \left[\frac{E}{\pi}(\beta_X + \beta_Y)\right]^{\frac{1}{2}}$ Bx + By ~ 52.7 m At the end of dipoles

<u>Αρ</u> (%)	A(B),	D''(mm)
+0.2	80' (100)	>41.0
0.0	115.*(100).**;	> 59.0 ₩
-0.2	80 (100)	>41.0 Pa

Table I.- Dipoles with no multipoles have larger dynamical aperture that shown (taken from reference 1)

ΔP/P (%)	A(B), A(C)	D (mm)
+0.2	99(100), 101(62)	50.8 ≤ D ≤ 51.8
0.0	109(100), 111(93)	56.0 € D∷ € 56.9 °°
-0.2	107(100), 109(100)	54.9 ≤ D ≤ 56.0 m

Table II .- Dipoles with Window Frame multipoles. Dynamical aperture.

Last table shows that at AP =0 the dynamical aperture of WFD is ~ 20 mm bigger than the corresponding DRD aperture.

2.- Physical Aperture of Dipoles.

To determine how stable is the beam near the operation emittance, a physi-

cal aperture of 300mm has been taken in the elements of the lattice. Next ta- 300mm ble shows these results.

$\Delta \rho / \rho$ (%)	A(B), A(C)	D(mm)
+0.2	48(100), 50(6)	24.6 ≤ D ≤ 25.7
0.0	50(100), 52(13)	25.7 € D ≤ 26.7
-0.2	44(100), 46(25)	22.6 \ D \ 23.6

Table III .- Dipoles with Window Frame multipoles. Physical aperture.

If we consider that the physical aperture for ideal dipoles (without multipoles) is of the same magnitude as for DRD, $(26.7 \le D \le 27.7)$, then for the WFD, the physical aperture is ~ 1 mm smaller. Finally we must to point out that this is not the real physical aperture. In order to determine it is necessary, as we already menciones it, to integrate the effects of multipoles in smaller pieces in each dipole.
