# IR Magnet Analysis

Jie Wei, BNL, June 17, 1996

## I. Introduction

## II. Field Quality Issues

- \* triplet quadrupole-corrector assembly
- \* dipole D0
- \* dipole DX
- \* other insertion-region magnets
- \* tune footprints and dynamic apertures

## III. Alignment & Assembly Issues

- \* multi-layer corrector
- \* corrector-quadrupole assembly
- \* ring installation
- \* dynamic apertures

## IV. Summary

# I. Introduction

- Due to intra-beam scattering growth at storage, beam size at low- $\beta^*$  ( $\beta^* = 1$  m) IR is much larger than the size anywhere at injection.
- With  $\beta^* = 1$  m, the storage performance is totally determined by the field and alignment quality of the IR magnets (triplet and D0) at high- $\beta$  locations.
- Beam-beam effects are insignificant.

Fig. 11-5. Expanded layout of half-insertion.

6 IP total

2 @  $\beta^* = 1\text{ m}$

4 @  $\beta^* = 10\text{ m}$

Table 1: Storage and injection beam parameter comparison.

Quantity	Injection	Storage
		( $\beta^* = 1\text{ m}$ )
$\epsilon_N$ (95%)	$10\text{ }\pi\text{mm}\cdot\text{mr}$	$40\text{ }\pi\text{mm}\cdot\text{mr}$
$\sigma_{\Delta p/p}$	$0.43 \times 10^{-3}$	$0.89 \times 10^{-3}$
$\beta_{arc}$	50 m	50 m
$\beta_{triplet}$	145 m	1400 m
$\sigma_{x,arc}$	2.5 mm	1.8 mm
<u><math>\sigma_{x,triplet}</math></u>	<u>4.5 mm</u>	<u>9.3 mm</u>

## II. Field Quality Issues

## \* Triplet quadrupole-corrector assembly

Planned compensation methods:

Figure of merit:

to minimize

$$\frac{(2J)^{\frac{n-1}{2}}}{\rho} \boxed{\int b_n \beta^{\frac{n+1}{2}} dl} \sim \frac{\Delta J}{J} \quad (\text{action kick})$$

- Choose lead-end orientation to minimize the effects of the stronger end.
- Use magnet body to compensate the ends on systematic  $b_5$  and  $a_5$ , taking into account the expected beam size variation in the magnet.
- Iterate quad cross-section, and shim individually using 8 tuning shims after warm/cold measurements.
- Sort golden quads and correctors for two low- $\beta^*$  IRs.
- Use IR correctors for orbit smoothing, decoupling, and higher order compensation.

## Current activities and results:

- Measurement data confirms that the choice of lead end orientation is very helpful.

a factor of 2 reduction in eff. strength

- Measurement data confirms that body-ends compensation is successful.

- Cold measurements of pre- and post-shimming quad harmonics indicate that tuning shims are highly effective in reducing multipole errors.

- Multiple measurements indicate dependence of certain multipole values on quench and thermal cycle. investigation under way

Post-shimming expected harmonics includes the uncertainties in shimming and measurement, and the dependence on quench and thermal cycle.

- Golden quads and correctors selected for low- $\beta^*$  IRs.

for sextant test

- Dependence of certain field multipole values on quench and thermal cycle makes higher-order dead-reckoned correction less effective.

- Notes:
1. Harmonics corrected with tuning shims are a2 through a5 and b2 through b5.
  2. a5 and b5 are custom optimized for each magnet. The above statistics is only for Q1 magnet. a5 and b5 are generally within 0.1 unit of desired value.
  3. a4 and b4 numbers are not reliable due to tilt in measuring (Warm measurements may be used instead).

## Triplet correctors:

- One horizontal and one vertical dipole correctors are located near focusing and defocusing quads of each IR triplet.

### **closed orbit**

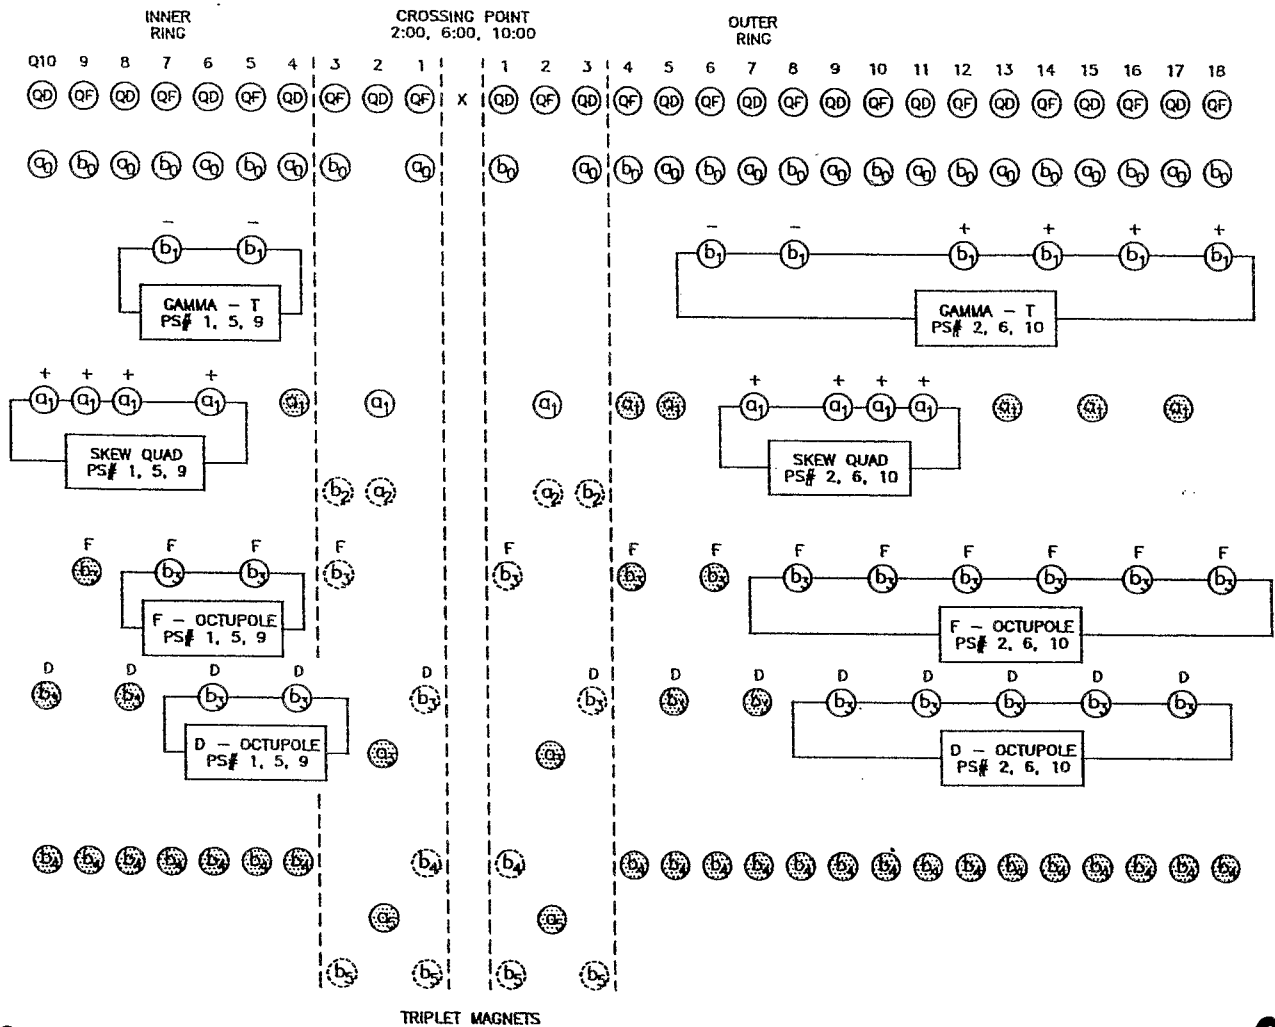

- Local decoupling can be done using dual-plane BPMs, including the two at every triplet.

### **coupling**

- Local higher-order correctors are dead-reckoned, based on cold measurement of every triplet quad.

**$b_3$  ,  $b_5$  ,  $b_7$  , etc.**

- It would be very helpful to develop and implement higher-order corrections based on live beam measurement, to overcome the dependence on thermal cycles.

## \* Dipole D0

- For  $\beta^* = 1$  m IRs, beam size is large at D0 ( $\beta \sim 600$  m); field quality is important.
- Tight geometry  $\implies$  challenge on cross-section design:  
cross-ring talk vs. iron saturation  
? **unknown**
- Inadequate iron  $\implies$  excessive  $b_2$  saturation in early D0s.
- These early D0s have been/will be designated as non-golden magnets used in higher  $\beta^*$  IRs  
cross-section iteration results in tolerable  $b_2$  and  $b_4$
- Triplet correctors are planned to be used for  $b_2$  correction of D0s.  
only one  $b_2$  corrector per triplet; less effective than pairs ( $b_3$  &  $b_5$ )  
two  $b_2$  correctors per IR can be used for semi-local correction

- Early D0s with large  $b_2$  saturation can not be used at low- $\beta^*$  IRs.

large action kick causes dynamic aperture problem

$$\frac{\Delta J}{J} \sim 0.013 \quad \text{for 50 particle}$$

- With new expected values, field quality is tolerable  
changes chromaticity by 0.6 units; manageable

## \* Dipole DX

- Since DX translates to accommodate for different collision scenarios, excessive beam orbit offset for proton-gold operation is no longer an issue.
- As far as field quality is concerned, gold-gold storage is relatively the most demanding scenario.

$6\sigma$  beam plus orbit offset at 63% coil radius;

$$\beta \sim 200 \text{ m}$$

- Expected uncertainty in body and end systematic  $b_2$ :  
insignificant effects in beam dynamics (chromaticity, tune foot-prints, dynamic aperture)  
feed-down easily correctable
- Field quality is not a problem.

strength (A)	$0 \pm 1.8$	$10.0 \pm 0.6$	$1.8 \pm 1.0$	$-11.2 \pm 1.0$

max. current available : 50 A

### III. Alignment & Assembly Issues

Triplet cryostat contains 2 dipoles (D0), 6 quads (Q1, Q2, Q3) and 6 corrector packages (C1, C2, C3) of both ring.

Each dipole or quad must move freely in the longitudinal direction during a thermal cycle, and must be strictly confined in the transverse direction.

#### Triplet assembly procedure:

- assemble and align four corrector layers into a corrector package
- sort on corrector and quad cold mass units, and attach corrector with quad
- align and install CQ units and D0 into the common cryostat in the tunnel

## \* Multi-layer corrector

Table 8: Improvement of magnetic field angle using pole shims (CRI101).

Layer	Dipole	Octupole	Decapole	Dodecapole
pre-shimming				
Integ. field angle (mr)	1.8	-2.7	-1.5	-0.9
post-shimming				
Integ. field angle (mr)	-0.2	0.6	-0.3	0.5

## \* Corrector-quadrupole assembly

- Sort on corrector and quad cold mass, both to optimize the field quality for low- $\beta^*$  IRs and to minimize the relative center offsets and roll between C and Q.

based on cold mass magnetic measurements

- After fiducialized, use antenna probe to locate the quad and corrector center relative to the cold mass fiducials.

**both antenna and colloidal methods used in**

- The current plan of eliminating relative CQ magnetic center offsets and roll during assembly, is challenged by technical difficulties. **C Q S**
- After sextant test, there will be more freedom of sorting CQ after it is finished and remeasured.

## \* Ring installation

- CQ assemblies and D0s are assembled in the cryostat in the tunnel.

Once closed, the quad center can not be independently adjusted.

- Using antenna techniques to relocate the quad and corrector center in the tunnel is desirable during final installation

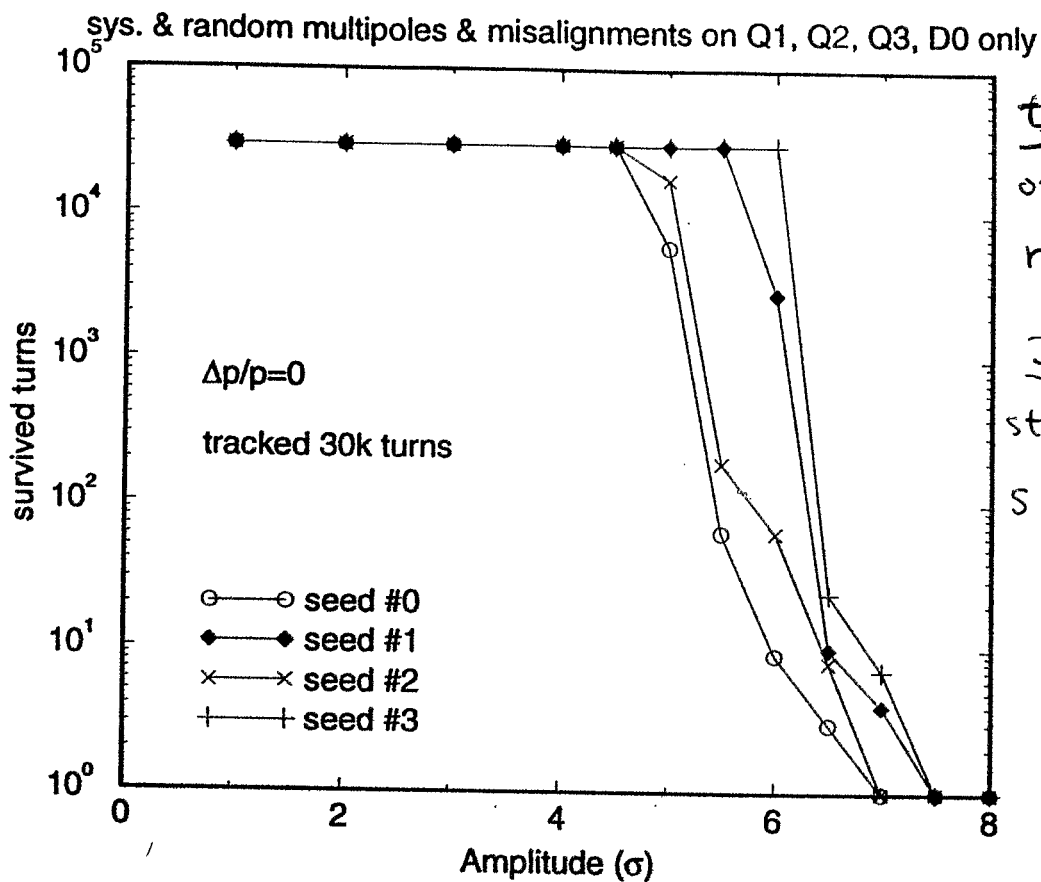

Table 9: Preliminary installation offsets (mean $\pm$ S.D.) of 77 arc CQSs and 88 arc dipoles.

Direction	Units	arc dipole	CQS element
North	[mm]	$-0.1 \pm 0.6$	$0.0 \pm 0.6$
East	[mm]	$-0.1 \pm 0.5$	$0.0 \pm 0.7$

## IV. Summary

- The measurement data of the completed triplet quads shows that tuning shims are very effective in reducing undesired harmonics.
- Further investigation on the dependence of field harmonics on quench and thermal cycle will make local IR higher-order correction more effective.
- Golden magnet selection is necessary in minimizing the negative impact of some early production triplet quads and D0 dipoles.
- An accurate alignment of triplet quads is crucial. Further development of the antenna techniques, both for CQ cold mass and in-tunnel measurement, is highly beneficial.
- Triplet corrector packages are extremely useful at storage for orbit smoothing, decoupling, and higher-order compensation, both for triplet quads and D0.
